aes_decrypt

WMMEGA FW >= 2.1147 WM-M2 FW >= 3.1147

Decrypt AES-encrypted data in **string**

Description

string aes_decrypt (string $data , int $length , string $key , string $iv)

Decrypts the string $data with length $length bytes. Pass the encryption key and iv value in the corresponding fields.

Parameter

$data: AES-encrypted string - it should be a multiple of 16 bytes long

$length: length of encrypted string

$key: Encryption key - this should be multiples of 16 bytes long. A 16 character string will yield 128-bit encryption.

$iv: This should be a unique 16 character string which will be used for the iv table

Return Values

Decrypted **string** (or **int** 0 for error)

Example

```
<pre><?

// create your custom key and IV value

  $key="0123456789abcdef";  // this is 16 bytes, or 128 bits
  $iv="abcdef0123456789";   // this needs to be 16 bytes long

  $data="This is my super secret encrypted string";

  // round up the string length to the nearest multiple of 16

  $len=intval((strlen($data)+1)/16)*16;
```

```
  // encrypt the data

  $encrypted_data = aes_encrypt($data,$len,$key,$iv);

  // store encrypted data into a base64-encoded string for easy tranport

  $base64_encrypted = base64_encode($encrypted_data);

  print("Your encrypted data is: ".$base64_encrypted);

  // this will yield:
  // fcPkxhW0UM4VIYB1CsbK/7wEBuC4WAwcO5tDBkcMXbfmf/gOHqdnrz5qHBRVY8Ls

  // base64 decode the string again

  $base64_decrypted = base64_decode($base64_encrypted);

  // we will use the calculated length from the encryption as the strlen()
function
  // may not yield a valid result if the encrypted string has a zero in it.

  // decryption  routine

  $plain_data = aes_decrypt(&$base64_decrypted,$len,$key,$iv);

  print("\r\nYour decrypted data is: ".$plain_data);

?>
```

The above example will output something similar to:

```
Your encrypted data is:
fcPkxhW0UM4VIYB1CsbK/7wEBuC4WAwcO5tDBkcMXbckp5yUp4a92BeD7VpVGwd1
Your decrypted data is: This is my super secret encrypted string
```
