

include

WMPRO, WMMINI FW >= 1.0 WMMEGA FW >= 2.0

Include a file within the current script at the current location

Description

`include (string $filename)`

This function includes and evaluates the specified file. When a file is included, the code it contains inherits the variable scope of the line on which the include occurs. Any variables available at that line in the calling file will be available within the called file, from that point forward. If the include occurs inside a function within the calling file, then all of the code contained in the called file will behave as though it had been defined inside that function. So, it will follow the variable scope of that function.

Parameter

\$filename: **String** containing the path and filename of the script to include and evaluate

Return Value

None

See Also

[call_user_func\(\)](#) - Call a user defined function with optional parameters

[exec\(\)](#) - Run a script with an optional delay

[function_exists\(\)](#) - Check if a function exists (native or custom)

[function](#) - Define a function
